BIG DADDY'S PYTHON TOOLBOX For 3.6+

CC BY NC SA vPro2A © 2017 John A. Oakey V100217a

Reserve Words

Comparsion / Conjunction

False, True, note caps; **==** (is same as) ; **none** (i.e., null), **and; not; or; in** list/tuple/string/dictionary/set; **is** or **is not** == comparison ↳ 'True' or 'False'

Definition

class create class: class className: see below
def creates a function: def functName(args):
del deletes variables, data containers, items in iterables: del mylist[x]
ITERABLE: a data container with changeable items

Module Management

import connects module, ex: import math
from get a single module function: from math import cos; print (cos(9)) *no module preface
as creates an alias for a function

Miscellaneous

pass (placeholder – no action)
with wrapper ensures **_exit_** method

Functions: See Page 2

def, return(obj), yield, next
def creates; inside functions **yield** is like **return** but returns a **generator** whose sequential results are triggered by **next**;
global x creates global var in a function
non local a variable inside a nested function is good in the outer function
lambda unnamed inline function, no return needed

```
a = lambda x: x*2
for z in range (1,6):
  print (a (z) )
```

Error Management

raise forces a specified exception
try except else finally assert used in error handling blocks

try: code with error potential
except: do this if you get the error
else: otherwise do this code
finally: do this either way
assert: condition=False raises **AssertionError**

Looping

while (some statement is True):
for expression:

```
alist=['Be','my','love']; x=iter(alist)
for i in range (len(alist)):
  print(i+1, next(x))
```

```
1 Be
2 my
3 love
```

range (start, stop, [step])
See data container functions
break ends loop, skips else, for holds val
continue skips to next loop cycle

Decision Making

if elif else

```
def ifExample(MyInt):
  if MyInt == 1:
    print('One')
  elif MyInt == 2:
    print('Two')
  else:
    print('Some other')
ifExample(int(input("1 or 2: ")))
```

The ternary if Statement
An inline **if** that works in formulas:
myval = (high **if** (high > low) **else** low) * 3

**Multi-line Statements **
Not needed within [], {}, or ()
Multiple Statements on a Line ; not with statements starting blocks like **if**

Functions not covered here:
vars(), dir(), super(), globals(), memoryview(), setattr(), bytearray(), classmethod(), locals(), __import__(), object(), hasattr(), issubclass(), isinstance(), compile(), hash(), complex(), bytes(), exec(), delattr(), property(), getattr(), staticmethod()
for **some** of those not covered here see:
www.wikipython.com

Major Built-In Functions

String Handling (↳=converts/returns)

str(object) ↳string value of object
repr(object) ↳printable representation string
ascii(str) ↳like repr but escape non-ascii
eval(expresion) ↳ value after evaluation
chr(i) ↳ character of Unicode [chr(97) = 'a']
ord(str)↳ value of Unicode character
input(prompt) ↳ user input as a string
len(—) ↳ length of str, items in list/dict/tuple
slice selection **[[start[:]] [[:]stop] [:step]]**
↳a new string object created by the selection
str.join('string seperator',[string list])
format(value [,format_spec]) ↳ value in a formatted string—**extensive and complex** - 2 syntactical structures (1) simple format only: **format(number/string,'format string')** (2) format and/or substitution: **'{:order or format string}'.format(objects);**

format string attributes/required order:

[[fill] align] [sign] [#-alt form] [0 forced pad] [width] [,] [.precision] [type]

Key **types**: **'f'**/'F' fixed point, default=6; **'g'**/'G' general; **'e'**/'E' exponential; **%** percent; **'c'** Unicode char; ex: format(number,**'0=+20,.3f'**)
↳ +000,000,012,345.679
Substitution using format():
"{variable to output} | {numeric format}...".format('string' or numeric values...)
'{0[x]}' selects the xth value in a tuple which format specifies: ex: print ('{0[x]}'.format(mytup))
Also: format dates with help of datetime module. **SEE WWW.WIKIPYTHON.COM ➔ TB4: Formatting Options**

Number Handling

abs(x) ↳ absolute value of x
bin(x) ↳ integer to binary **bin(5)=** '0b101' (one 4, no 2's, one 1) **bin(7)[2:] = '111'**
divmod(x,y) takes two (non complex) numbers as arguments, ↳a pair of numbers - quotient and remainder using integer division.
float(x) ↳ a floating point number from an integer or string **A="1.1"; print(float(A)*2)** ↳2.2
hex(x)↳integer to hex string **hex(65536)** ↳**0x10000** or **hex(x)[2:]='10000'** also **oct(x)** ↳int to octal
int(x) ↳ integer from a decimal, string, hex
pow(x,y [,z]) ↳ x to y, if z is present returns x to y, modulo z **pow(2,7)=128, pow(2,7,3)=2**
round(number [,digits]) ↳ floating point number rounded to digits; Without digits it returns the nearest integer. **Round(3.14159,4)=3.1416**

Miscellaneous Functions

bool(x) ↳ True/False, ↳ False if x is omitted
callable(object) ↳True if object is callable
help(object) invokes built-in help system, (for interactive use)
id(object) ↳unique object integer identifier
print(*objects, sep=' , end='\n', file= sys.stdout, flush=False) prints objects separated by sep, followed by end;

File open (and methods)

wholeFilePath = "C:\\file\\test\\mytest.txt"
fObj=**open**(file[,mode],buffering]) basic modes: **r, r+, w, w+, a** ..more helpful object methods: **.read(size), .readline(), .readlines(), .write(string), .close(), .splitlines ([keepends]), list(openfile)**

```
with open("C:\Python351\Jack.txt",'r+') as sprattfile:
  sprattlist=sprattfile.read().splitlines() *<- removes '/n'
  print(sprattlist)
```

↳['Jack Spratt', 'could eat ', 'no fat.', 'His Wife', 'could eat', 'no lean.'] *The WITH structure auto closes the file.*

Operators

Math: = (= can also value swap; a, b = b, a), **+, -, *, /, //** (floor or truncated division - no remainder), ** (exponent), **%** (mod or modulo returns the remainder) x = 8%3; print(x) ↳2
Boolean/Logical: and, or, not *not(a [and/or] b)*
Comparison: == (same as), **<, <=, >, >=, is, is not, !=**(is not equal); operators can be chained
Membership: in , not in
Identity: is/is not checks for same object
Bitwise: & (and), | (or), ^ (xor 1 not both), ~ flips last bit << (shift left), >>(shift right) >>> bin(0b0101 <<1) ↳'0b1010'
Assignment: (execute & assign) =, //=, -=, +=, *=, /=, **=, %=
Sequence Variable Opers (for strings) + concatenation (strx + stry) , * repetition (strx*3)=strx+strx+strx; **s[i]** single slice, **s[i:j:k]** range slice from, to, step -> *starts at 0, end - count from 1; ie 1 more than qty needed* ☹
r*'str'* **raw** string/byte obj suppresses ESC chrs

Escape Characters
Nonprintable characters represented with backslash notation: **r** ignores esc chars; **\n** Newline, **\b** Backspace, **\s** Space, **\cx** or **\C-x** Control-x, **\e** Escape, **\f** Formfeed, **\t** Tab, **\v** Vertical tab, **\x** Character x, **\r** Carriage return, **\xnn** Hexadecimal notation, n is in the range 0-9, a-f, or A-F; **many more**

Helpful String Methods

.find(sub[, start[, end]])
↳First char BEFORE sub is found or -1 if not found ex: print('Python'.find("th")) ↳ 2
.rfind(sub[, start[, end]])
↳ the **highest index** in the string where substring sub is found, contained within slice [start:end]. Return -1 on failure.
.capitalize() ↳first character cap'ed
.lower() ↳ a copy of the string with all text converted to lowercase; **.upper()**
.center(width[, fillchar])
string is centered in an area given by width using fill character 'fillchar'
.ljust(width [, fillchar]) or **.rjust()**
.count(sub[, start[, end]])
number of substrings in a string
Attributes: **isalnum, isalpha, isdecimal, isdigit, isidentifier, islower, isnumeric, isprintable, isspace, istitle, isupper** - may be null, ↳ True if all char meet condition and variable is at least one char in length
.replace(old, new[, count])
↳ a copy of the string with substring old replaced by new. If opt argument count is given, only first count are replaced.
.strip([chars]) ↳ a copy of the string with the leading and trailing characters removed. The chars argument is a string specifying the set of characters to be removed. If omitted or None, the chars argument removes whitespace. Also **lstrip / rstrip**
.split() - returns list of words extracted by an interveining space.
str.join(iterable) - concatenates strings in iterable; str is the separator
Others include: casefold, join, encode, endswith, expandtabs, format, format_map, index, partition, maketrans, rindex, rpartition, rsplit, , splitlines (keepends), **title, startswith, swapcase, translate, upper, zfill**

BIG DADDY'S PYTHON TOOLBOX For 3.6+

CC BY NC SA vPro2A © 2018 John A. Oakey V100217a

Data Containers Methods / Operations

In notes below: (i/j/k-> an **index**; x->value or **object**; L/T/D/S-> an **instance** of a **list, tuple, dictionary**, or **set**.

LISTS: **.append**(x); **.copy**(); *Create* L=**[x,x,…]**, L=**[]**, L=**list(tuple)**; **.clear**; **.count**(x); **del** L; **.extend**(x,x,…); *Determine membership* if x **in** L; **insert**(i,x); **len**(L); **.max**(L); **.min**(L); **.pop**(); **.pop**(i); **.remove**(x); *Replace item* L**[i]=x**, *Replace multiple items* L**[i:j]**=[x,x…] ; *Retrieve index, 1st value of x* **indexno=** L**.index (x[**, *at/after index* i [,*before index* j **]])** ; **.reverse**; **.sort**(key= none, reverse= False); *Create iterative generator* **V=iter**(L) , *trigger iteration* **next**(V, default)

List Comprehensions

Make a new list with item exclusions and modifications from an existing list/tuple: brackets around the expression, followed by 0 to many **for** or **if** clauses; clauses can be nested:

newLst = **[**[modified]item for item in OldLst if some-conditional-item-attribute of (item)**]** *example:*

```
atuple=(1,-2,3,-4,5)
newLst= [item*2 for item in atuple if item>0]
print(atuple, newLst)   (1, -2, 3, -4, 5) [2, 6, 10]
```

if modifying items only: up1list =[x+1 for x in L]

TUPLES: *Add items* **+=**; *Add singe item* **+=(x,)**; **.count**(x); *Create* T=**(x,[x],(x),…)** *members can be lists & other tuples, parens not required*; *Create tuple from a list* **T=tuple(L)** *; clear values* **T=()**; **del** T; *Item index* **i=T.index(x[**,*at or after index* i [,*before index* **j]])**; *Iteration generator* v=**iter(T)**, *next iteration* **next**(v) ; **len(T)**; **.max**(T); *Member* x **in** T; **.min**(T); *Retrieve values* **x,x,…=T[i:j]**; *Slice* T**[i:j]** *start is 0, end j-1*; T**[::-1]**; **sorted** (T, **reverse=False)**

DICTIONARIES: *Create* D**={k:v, k:v,…}**, **=dict.fromkeys (keys/list[,values])**; *Add D2 to D* D.**update**(D2); D.**copy()**; D.**clear()**; **del** D; *Delete key and value* **del D[k]**; D.**get**(k[,x]) *like D[k] but D.**get(k,x)*** x if no k; *Iteration variable* V=**iter**(D), *trigger iterations* **next**(v); **len**(D); *Member* x **in** D, x **not in** D, D.**has_key**(x); D.**pop**(k[,default]); D.**popitem()**; *Returns* D.**items(), D.keys(), D.values()**; *Returns the v mapped to k* **D[k]**; D.**setdefault(k[,default])** *if k is in the dictionary return the key value, if not, insert it with default value and return default*

SETS: ***no duplicates*** *Create* S=**set**(), S=**{x,x,x}**, S=**set**(**L**) *from list*, S=**'string'** *unique letters*; **.add**(x); **.clear()**; **.copy()**; **del** S; **.difference**(S2); **.discard**(x); **.intersection** *set('abc').intersection('cbs')*; **.isdisjoint**(S2) *True if no common items*; *Contained by* **.issubset**(S2) *or* **S<=S2** *y*; *Contains* **.issuperset**(S2) *or* **S>=S2, S>S2**; **len**(S); **.pop()**; **.remove**() *KeyError if not present*; *iteration variable* v=**iter**(S); *trigger iteration* next(v); *member* S **in**, S **not in**; **.union**(other sets); **.update**(other sets)

FROZEN SET: *a set immutable after creation* S=**frozenset**([iterable])

comments and suggestions appreciated:
john@johnoakey.com

Data Container Functions

all(iterable) ↳ True if all elements are True
any(iterable) ↳ True if any element is True
both all and any are FALSE if empty

enumerate(iterable, start = 0) ↳list

```
alst = ['x','y','z']
print(list(enumerate(alst)))
 [(0,'x'), (1,'y'), (2,'z')]
```

Use enumerate to make a dictionary: ex: mydict = dict(enumerate(mylist)) **Dictionaries** enumerate keys & yield values unless values specified; print (**dict**(enumerate(mydict.values()))) yields keys

type([iterable]) ↳a datatype of any object

max(type) min(type)

sum(iterable [, start]) must be all numeric, if a=[8,7,9] then sum(a) returns 24

sorted(iterable [,key=][,reversed]) reversed is Boolean with default False; strings without key sorted alphabetically, numbers high to low; key examples: print (sorted(strs, key=len)) sorts by length of each str value; ex: key= strs.lower, or key = lambda tupsort: tupitem[1]

reverse() inverts list order; mylist.**reverse()**

reversed() reverses access order—list or tuple

```
alist=["Amy","Bo","Cy"]
alist.reverse()
for i in alist:
  print(i)
for i in reversed(alist):
  print(i)
```

```
Cy
Bo
Amy
Amy
Bo
Cy
```

Reverse a word

```
word = "Python"
iterword = iter(word)
newword =""
for i in reversed(word):
  newword +=i
print(word, newword)
```

range (stop) or **(start, stop [,step])**

```
alist=["Amy","Bo","Cy"]
for i in range (0,len(alist)):
  print(i, alist[i])  #note slice
```

```
0 Amy
1 Bo
2 Cy
```

iter and **next(iterator [,default])** Create iterator then fetch next item from iterator. Default returned if iterator exhausted, otherwise StopIteration raised.

```
alist=["Amy","Bo","Cy"] ; IterNum = iter(alist)
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
```

```
Amy
Bo
Cy
listend
```

map(function,iterable) can take multiple iterables but function must take just as many

```
alist=[5,9,13,24]
x = lambda z: (z**2 if z**2 < 150 else 0)
itermap = map(x,alist)
for i in alist:
    print(next (itermap))
```

zip merges two iterables left to right

filter(function, iterable) iterator for element of iterable for which function is True.

getattr(object, 'name' [, default])
setattr(object, 'name', value)

CLASS: (Your very own complex data object **blueprint**.)

Line 1: required in red, optional in green
command key word inheritance - creates a "derived class"
class myClassName (inheritance):
your class name-class definition header colon

Class creates a brand new namespace and supports **two operations**: attribute reference and instantiation

Next Lines:(statements) usually **(1)** a docstring, like '''Docstring example''' **(2)** instantiation, using a special method: **__init__(**self, arguments**)** which is autoinvoked when a class is created; arguments are passed when a class instantiation is called:

```
def __init__(self, passed arguments):
    variable name assignments, etc.
```

(3) function definitions, local variable assignments

```
class mammalia(object):
  def __init__(self, order, example):
    self.ord = order
    self.ex = example
    self.cls="mammal"
  def printInfo(self):
   info="class/order: "+self.cls+"/"+self.ord+\
        ", Example:" +self.ex
   print(info)
x = mammalia("Cetacea","whales")
x.printInfo()
```

↳ class/order: mammal/Cetacea, Example: whales

Creating a Function: required components - red, optional - green

Line 1:
command key word arguments
Def name (input or defined params):
your new function's name colon
All subsequent lines must be indented
Line 2: a docstring
Line 2 or 3 to ?: code block
Usual line last: **return**(expression to pass back) *keyword to pass result*
BUT... a *generator* can be passed using **yield**: for example:

```
aword = "reviled"
def makegen(word):
    marker = len(word)
    for letter in word:
        yield (word[marker-1: marker])
        marker=marker-1
for letter in makegen(aword):
    print(letter)
```

deliver

*args and *kwargs:

used to pass an unknown number of arguments to a function.
***args** is a **list** ***kwargs** is a **keyword -> value pair** where keyword is not an expression

```
def testargs (a1, *argv):
  print('arg#1: ',a1)
  for ax in range(0,len(argv)):
    print ("arg#"+str(ax+2)+" is "+argv[ax])
testargs('B', 'C', 'T', 'A')
def testkwargs(arg1, **kwargs):
    print ("formal arg:", arg1)
    for key in kwargs:
        print ((key, kwargs[key]))
testkwargs(arg1=1, arg2="two", dog='cat')
```

```
arg#1: B
arg#2 is C
arg#3 is T
arg#4 is A
```

```
formal arg: 1
('dog', 'cat')
('arg2', 'two')
```

Useful Module/Functions

Python Standard Library Module
See wikipython.com vetted module examples
https://docs.python.org/3.5/library

math: like Excel math functions ceil(x), fsum(iterable), sqrt(x), log(x[,base]), pi, e, factorial(x)

random: seed([x]), choice (seq), randint(a, b), random() - floating point [0.0 to 1.0] **sys** exit ([]), path, platform **datetime** date.today(), datetime.now(), **time** localtime(), clock(), asctime (struct_time tuple), sleep(secs)

calendar—a world of date options

```
import calendar
mymo = calendar.TextCalendar()
mymo.setfirstweekday(calendar.SUNDAY)
mymo.prmonth(2018,7)
```

```
    July 2018
Su Mo Tu We Th Fr Sa
 1  2  3  4  5  6  7
 8  9 10 11 12 13 14
15 16 17 18 19 20 21
22 23 24 25 26 27 28
29 30 31
```

Works best with a mono-spaced font like **Consolas** .

tkinter also see **ttk; tix**; see TB4 on **wikipython; tkinter NOT Tkinter**

RPi.GPIO - control Raspberry Pi pins via Python; See also: **os** deep operating system access; **array** arrays; **tarfile/zip-file** - file compress-ion; **wave** - interface to wav format; **csv** access data: comma separated values

A note on format: (1) **new f string options** available in version **3.6** (2) the old string % syntax will eventually be deprecated: print("$ %.2f buys %d %ss"%(1.2,2,'hot dog')) *try it*
