

## Reserve Words

### Comparison / Conjunction

**True, ==** (equal), **False, none** (i.e., null), **and, not, or**, in list, tuple, string, dictionary  
**is** True if same object, **is not**

### Definition

**class** create a class  
**def** create a function  
**del** items in lists (del mylist[2]), whole strings, whole tuples, whole dictionaries

### Module Management

**import** connects module, ex: import math  
**from** gets a function from math import cos  
**as** creates an alias for a function

### Miscellaneous

**pass** (placeholder – no action)  
**with** wrapper ensures **\_exit\_** method

### Functions

**def, return(obj), yield, next**  
def creates; inside functions **yield** is like **return** but returns a generator whose sequential results are triggered by **next**;  
**global** declares global var in a function  
**non local** a variable inside a nested function is good in the outer function  
**lambda** anonymous inline function with no return statement

```
a = lambda x: x*2
for z in range (1,6):
    print (a (z))
```

### Error Management

**raise** forces a ZeroDivisionError  
**try except else finally assert** used in error handling blocks  
**try:** code with error potential  
**except:** do this if you get the error  
**else:** otherwise do this code  
**finally:** do this either way  
**assert:** condition=False raises **AssertionError**

### Looping

**while** (some statement is true)  
**for** alist=['Be','my','love']  
for wordnum in range(0,len(alist)):  
    print(wordnum, alist[wordnum]) #slice  
**range (start, stop, [step])**  
See data container functions  
**break** ends the smallest loop it is in;  
**continue** ends current loop iteration

### Decision Making

**if elif else**  
def if\_example(a):  
    if a == 1:  
        print('One')  
    elif a == 2:  
        print('Two')  
    else:  
        print('Some other')

### The Ternary if Statement

An inline if that works in formulas:  
myval = (high if (high > low) else low) \* 3

### Multi-line Statements \

Not needed within [], {}, or ()

**Multiple Statements on a Line ;** not with statements starting blocks like **if**

### CLASS: Your own data container. DEFINE DESIGN:

```
class Name (inheritance object)
def __init__(self, mandatory variables,...)
    accessname = mandatory variable ...repeat as necessary
    Other functions: "getaccessname(self)", or "return self.variable"
CREATE INSTANCE:
MyInstanceName = ClassName(self)
ACCESS INSTANCE DATA:
Print(MyInstanceName.accessname in get function)
```

## Major Built-In Functions

**String Handling** (↪=converts/returns)

**str(object)** ↪ string value of object  
**repr(object)** ↪ printable representation string  
**ascii(str)** ↪ like repr but escape non-ascii  
**eval(expression)** ↪ value after evaluation  
**chr(i)** ↪ character of Unicode [ chr(97) = 'a']  
**ord(str)** ↪ value of Unicode character  
**input(prompt)** ↪ user input as a string  
**len(—)** ↪ length of str, items in list/dict/tuple  
string object [start: stop [:step]] ↪ a new object created by slice selection,  
**str.join('string separator',[string list])**  
**format(value [,format\_spec])** ↪ value in a formatted string—**extensive and complex** - 2 syntactical structures (1) simple format only:  
**format(number/string,'format string')**  
(2) format and/or substitution: **'{:order or format string}'.format(objects);**  
format string attributes/required order:

**[[fill] align] [sign] [#-alt form] [0 forced pad] [width] [,] [.precision] [type]**

Key types: 'f'/'F'~ fixed point, default 6; 'g'/'G'~ general; 'e'/'E'~ exponential; %~percent; 'c'~ Unicode char; ex: format(number, '0=+20,.3f')

↪ +000,000,012,345.679  
Substitution using format():  
" {variable to output} | {numeric format}..." .format ('string' or numeric values...)

'{0[x]}' selects the xth value in a tuple which format names: ex: print ('{0[x]}' .format(mytuple))

Can format dates with help of datetime module.

SEE WWW.WIKIPYTHON.COM : OUTPUT TOOLBOX

### Number Handling

**abs(x)** ↪ absolute value of x  
**bin(x)** ↪ integer to binary bin(5)= '0b101'  
(one 4, no 2's, one 1) bin(7)[2:] = '111'  
**divmod(x,y)** takes two (non complex) numbers as arguments, ↪ a pair of numbers - quotient and remainder using integer division.  
**float(x)** ↪ a floating point number from an integer or string  
**hex(x)** ↪ integer to hex string hex(65536)=0x10000  
or hex(x)[2:]='10000' also **oct(x)** ↪ int to octal  
**int(x)** ↪ integer from a decimal, string, hex  
**pow(x,y [,z])** ↪ x to y, if z is present returns x to y, modulo z pow(2,7)=128, pow(2,7,3)=2  
**round(number [,digits])** ↪ floating point number rounded to digits; Without digits it returns the nearest integer. Round(3.14159,4)=3.1416

### Miscellaneous Functions

**bool(x)** ↪ true/false, ↪ false if x is omitted  
**callable(object)** ↪ true if object is callable  
**help(object)** invokes built-in help system, (for interactive use)  
**id(object)** ↪ unique object integer identifier  
**print(\*objects, sep=' ', end='\n', file=sys.stdout, flush=False)** prints objects separated by sep, followed by end;  
**File open (and methods)**  
wholeFilePath = "C:\\file\\test\\mytest.txt"  
fObj=open(file[,mode],buffering)) basic modes: r, r+, w, w+, a .more file object methods:  
**.read(size), .readline(), .readlines()** or **list(), .write(string), .close(), .splitlines([keepends])**,  
with open("C:\\Python351\\Jack.txt", 'r+') as sprattfile:  
    sprattlist=sprattfile.read().splitlines() \*-<- removes '/n'  
    print(sprattlist)

↪ ['Jack Spratt', 'could eat', 'no fat.', 'His Wife', 'could eat', 'no lean.']\*The WITH structure auto closes the file.

## Operators

**Math:** =, +, -, \*, /, // (floor or truncated division - no remainder), \*\* (exponent), % (mod or modulo returns the remainder) x = 8%3; print(x) ↪ 2

**Boolean/Logical:** and, or, not

**Comparison:** == (same as), <, <=, >, >=, is, is not, != (is not equal)

**Sequence Variable Opers +** concatenation, \* repetition, S[i] slice, S[i:j:k] range slice from,to,step - start 0

**Membership:** in, not in

**Identity:** is/is not checks for objects being the same object

**Bitwise:** & (and), | (or), ^ (xor 1 not both), ~ flips last bit << (shift left), >> (shift right) >>> bin(0b0101 <<1) ↪ '0b1010'

**Assignment:** (execute & assign) =, // =, AND assignment operators [ -=, +=, \*=, /=, \*\*=, %= ] (only + & - work for strings) r'str' raw string suppresses ESC chrs)

### Other Functions

vars(), dir(), super(), globals(), setattr(), bytearray(), classmethod(), zip(), locals(), \_\_import\_\_(), object(), memoryview(), hasattr(), isinstance(), issubclass(), compile(), hash(), complex(), bytes(), exec(), delattr(), property(), getattr(), staticmethod()

## String Methods

**.find(sub[, start[, end]])**  
↪ First char BEFORE sub is found or -1 if not found ex: aword = "python"; print (aword.find("th")) ↪ 2  
**.capitalize()** ↪ first character cap'ed  
**.lower()** ↪ a copy of the string with all text converted to lowercase.  
**.center(width[, fillchar])**  
string is centered in an area given by width using fill character 'fillchar'  
**.ljust(width [, fillchar])** or **.rjust()**  
**.count(sub[, start[, end]])**  
number of substrings in a string  
**.isalnum() .isnumeric() .isalpha .isdigit() .isspace() .islower() .isupper .isprintable()** may be null  
↪ true if all char meet condition and variable is at least one char in length  
**.replace(old, new[, count])**  
↪ a copy of the string with substring old replaced by new. If opt argument count is given, only first count are replaced.  
**.rfind(sub[, start[, end]])**  
↪ the **highest index** in the string where substring sub is found, contained within slice [start:end]. Return -1 on failure.  
**.strip([chars])** ↪ a copy of the string with the leading and trailing characters removed. The chars argument is a string specifying the set of characters to be removed. If omitted or None, the chars argument removes whitespace.  
**.zfill(width)** ↪ a copy of the string left filled with ASCII '0' digits to make a string of length width. A leading sign prefix ('+'/'-') is handled by inserting the padding after the sign character rather than before. Original string is returned if width is less than or equal to len(str).  
**str.split()** - returns list of words extract -ed by an intervening space

## Data Containers Methods / Operations

Below: (i)/k-> index; x->item or object; L/T/ D/S->name of list, tuple, dictionary, or set.

**LISTS:** create - `[x,x,...]`; `.insert(i,x)`; `append(x)`; `L[i]=x`; `.extend(x,x,...)`; `.remove(x)`; `del L`; `.pop()`; `.pop(i)`; `L[i]=replacement x`; `L[i:j]=[x,x,...]` replace multi-items; `i=L.index(x[at or after index i [before index j]])` retrieve index number of first value of x; `V=iter(L)` creates iteration generator; `next(V,default)` to step thru iteration; `len(L)`; `.count(x)`; `.max(L, min(L))`; if v in L determine membership; `.copy()`; `sort(key=None, reverse=False)`; `.reverse`; `.clear`; `L=[]`; `L=list(tuple)`

**TUPLES:** create - `(x,[x],(x),...)` objects can include lists and other tuples; `+=` add items; `+=(x)` add single item; `tuple[i:j]` start is 0, end j-1; `x,x,...=T[i:j]` retrieve values; `i=T.index(x[at or after index i [before index j]])`; for int in T; `v=iter(T)` creates iteration generator; `next(v)` next iteration; `len(T)`; `.count(x)`; `.max(T)`; `.min(T)`; x in T; `sorted(T, reverse=False)`; `T[::-1]`; `T=()` clears all values; `del T`; `T=tuple(somelist)` creates a tuple from a list

**DICTIONARIES:** create - `{k:v, k:v,...}`; `D=dict.fromkeys(keys/list[,values])`; `D.update(D2)` adds D2 to D; `D[k]=v` returns value of k; `del D[k]` deletes key and item; `D.pop(k[,default])`; `D.popitem()`; `D.items()`; `D.keys()`; `D.values()`; `D.get[k]` same as `D[k]`; `v=iter(D)` creates iteration variable; `next(v)` step thru iterations; `len(D)`; v in D; v not in D; `D.has_key(v)`; `D.copy()`; `D.clear()`; `del D`; `D.setdefault(k[,default])` if k is in the dictionary return the key value, if not, insert it with default value and return default

**SETS:** create: `S=set(x,x,...)` no duplicates; `S=set(L)` use list as set items; `S=a string` yields unique letters; `S=set()`; `.union(S2)`; `.update(S2)`; `.intersection(S2)`; `.add(x)`; `.difference(S2)`; `.remove(x)` gives `KeyError` is not present; `.discard(x)`; `.pop()`; `.copy()`; `.isdisjoint(S2)` true if no common items; `.issubset(S2)` or `S<=S2` contained by; `S<S2` true if both `S<=S2` and `S!=S2` (is not equal); `.issuperset(S2)` or `S>=S2`; `S>S2`; `v=iter(S)` create iteration variable; `next(v)`; `len(S)`; `S in`; `S not in`; `.clear()`; `del S`

**FROZEN SET:** a set immutable after creation `S=frozenset([iterable])`

## Escape Characters

Nonprintable characters represented with backslash notation: r ignores esc chars; `print(r'test1\t\n test2')` test1\t\n test2  
`\a` bell or alert, `\b` Backspace, `\s` Space, `\cx` or `\C-x` Control-x, `\e` Escape, `\M-\C-x` Meta-Control-x, `\f` Formfeed, `\n` Newline, `\t` Tab, `\v` Vertical tab, `\x` Character x, `\r` Carriage return, `\nnn` Octal notation, where range of n is 0-7 `\xnn` Hexadecimal notation, n is in the range 0-9, a-f, or A-F

## Data Container Functions

**all(iterable)** TRUE if all elements are true  
**any(iterable)** TRUE if any element is true  
 both all and any are FALSE if empty  
**enumerate(iterable, start = 0)** list

```
alist = ['x','y','z']
print(alist enumerate(blist))
# [(0,'x'), (1,'y'), (2,'z')]
```

**type([iterable])**  
 a datatype of any object

**max(type) min(type)** - not for tuples  
**sum(iterable [, start])** must be all numeric, if a=[8,7,9] then sum(a) returns 24

**sorted(iterable [,key=],[reversed])**  
 reversed is Boolean with default False; strings without key sorted alphabetically, numbers high to low; key examples: `print(sorted(strs, key=len))` sorts by length of each str value; ex: `key=strs.lower`, or `key=lambda tupsort: tupitem[1]`

**reverse()** reverses in place; `mylist.reverse()`  
**reversed()** reverses access order—list or tuple

```
alist=["Amy","Bo","Cy"]
alist.reverse()
for i in alist:
    print(i)
for i in reversed(alist):
    print(i)
```

```
word = "Python"
iterword = iter(word)
newword = ""
for i in reversed(word):
    newword += i
print(word, newword)
```

**range (stop) or (start, stop [,step])**

```
alist=["Amy","Bo","Cy"]
for i in range(0,len(alist)):
    print(i, alist[i]) #note slice
```

0 Amy  
1 Bo  
2 Cy

**iter and next(iterator [,default])** Create iterator then fetch next item from iterator. Default returned if iterator exhausted, otherwise StopIteration raised.

```
alist=["Amy","Bo","Cy"]
IterNum = iter(alist)
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
print(next(IterNum, "listend"))
```

Amy  
Bo  
Cy  
listend

**map(function,iterable)** can take multiple iterables but function must take as many

```
alist=[5,9,13,24]
x = lambda z: (z**2 if z**2 < 150 else 0)
itermap = map(x,alist)
for i in alist:
    print(next(itermap))
```

**filter(function, iterable)** iterator for element of iterable for which function is True.

**getattr(obj, 'name' [, default])**  
**setattr(object, 'name', value)**

## List Comprehensions

make a new list with item exclusions and modifications from an existing list: brackets around expression followed by 0 to many for or if clauses; can be nested  
 NewLst = `[[modified]item for item in OldLst if some-conditional-item-attribute of (item)]` or if modifying x only, ex: `up1Lst=[x+1 for x in ylst]`

**\*args and "kwargs":** are used to pass an unknown number of arguments to a function. \*args is like a list, \*kwargs is a keyword->value pair, but keyword cannot be an expression

```
def testargs(a1, *argv):
    print('arg#1: ',a1)
    for ax in range(0,len(argv)):
        print("arg#" + str(ax+2) + " is " + argv[ax])
testargs('B', 'C', 'T', 'A')
def testkwargs(arg1, **kwargs):
    print("formal arg:", arg1)
    for key in kwargs:
        print((key, kwargs[key]))
testkwargs(arg1=1, arg2="two", dog='cat')
```

arg#1: B  
arg#2 is C  
arg#3 is T  
arg#4 is A

formal arg: 1  
'dog', 'cat'

## Useful Modules

Python Standard Library Module  
 Index with links:  
<https://docs.python.org/3.5/library/>  
**math** like Excel math functions `ceil(x)`, `.fsum(iterable)`, `sqrt(x)`, `log(x[,base])`, `pi`, `e`, **random** seed `([x])`, `choice(seq)`, `randint(a,b)`, `randrange(start, stop [,step])`, `.random()` - floating point `[0.0 to 1.0]` **sys** stdin standard input, stdout std output, `exit` (error msg) **datetime** `date.today()`, `datetime.now()`, `time asctime(t)`, `clock()`, `sleep (secs)`

**calendar**—a world of date options

>>> **import calendar**

>>> **c =**

**calendar.TextCalendar**  
**(calendar.SUNDAY)**

>>> **c.pmonth(2016, 9)**

```
September 2016
Su Mo Tu We Th Fr Sa
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30
```

This only works with a mono-spaced font like Consolas .

**tkinter** Python's defacto GUI; also see **ttk**; **tix**; Older version was: Tkinter (capital T)

**os** deep operating system access `open(name[,mode[,buffering]])` modes: 'r' reading, 'w' writ-ing, 'a' appending, binary append

'b' like 'rb' array work with mathematical arrays; **tarfile/zip-file** - file compression; **wave** - interface to wav format; **RPi.GPIO**

## re-Regular Expressions module

re is a language in itself roughly the size of Python. It supports pattern matching on (1) module-level—for 1 time use and (2) compiled expressions. To compile an expression set a variable like `mypat = re.compile(pattern)` then use it to **search** or **match**. Match searches from first character only. Also you can **findall()** and **finditer()**.

`import re` if not found 'None'; attris error `teststring = "Taking Math 101 is fun!"`

`mypat = re.compile(r'd+', flags=0)`  
`myso = mypat.search(teststring)`

```
print(myso)
print('group()', myso.group())
print('start()', myso.start())
print('end()', myso.end())
print('span()', myso.span())
...or don't compile it...
```

`print(re.search(r'd', teststring).start())`  
**Special characters** `^ $ * + ? { } [ ] \ | ( )`

**Use Python r (raw) to process \ commands**

`r'(pattern)'` matches literally: . any except newline `\d` decimal digit `\D` non-decimal `\w` any alphanumeric `\W` non-alphanumeric `\s` any white space chr `\S` non-whitespace `*` 0 or more `+` 1 or more `?` 0 or 1 `X{n}` exactly n 'X' chars `X{m,n}` between m & n `X's` end of str `|` OR: `a|b` matches a OR b (...) whatever re is in the parens `(?abcdef)` one or more letters in parens `(?=...)` a look ahead assertion, "only if" `(?!...)` negated look-ahead assertion, "not if" `\A` match only at start of string `\Z` match only end of string `\b` empty string at the start/end of a word `[]` contains a set of chars to match: `[-a-c]` matches a,b or c special chars lose meaning inside `[]`, `^` as 1st char starts complimentary match

**Flags:** **DOTALL** any char, **A** escapes match **ASCII**, **IGNORECASE**, **MULTILINE** affecting `^`, **VERBOSE** **About Backslashes:** use the `\` character to indicate special forms or allow a character's use without invoking its special meaning—be aware this conflicts with Python's usage of the same character in string literals.

**To test for true** result, use bool operator: if `bool(re.search(r'd', teststr))=True:`
