print() is a function
print(*objects*, separator="", end='\n')
print("Hello World!")   ↳   **Hello World!**

Coding Operators

** **Multiline (explicit join) Statements:
Not needed within [], {}, or ()
; **Multiple Statements on a Line:** not
used/needed with **for, if, while**
**line comment**
''' **block**
            comment   **"""**

Operators

Math: =(execute/assign) value swap
a,b=b,a; **+; -; *; /; ** (exp); +=
a+=b ↳ a=a+b; **-=; *=; **=; /=;
//=** (floor div-truncated no remainder;
% (**mod**ulo) ↳ remainder from division;
Boolean: **False, True** (0 , 1)
Logical: and, or, not *modify compare*
Comparison: == (same as); != (is
not equal); <; <=; >; >=; **is; is
not**; all ↳ **Boolean** values — **(T/F)**
Membership: in; not in; - a list,
tuple, string, dictionary, or set
Identity: is; is not the same *object*
Binary: & (and); **|** (or); **^** (xor - 1
not both); **~** inversion, = -(x+1);
<< (shift left); **>>**(shift right)
 bin(0b0101 <<1) ↳ '0b1010'
Sequence Variable Operators
strings: + -concatenate, *** -** repeat;
single char slice s**[i]**; **range slice** s
[i:j:k] from, **to**, **step** -> *start at i,
end j-1, increment by count*

Number Tools

abs(x) ↳ absolute value of x
bin(x)↳ int to binary bin(5)= '0b101'
(a 4, no 2's, a 1); bin(7)[2:] = '111'
divmod(dividend,divisor) from
noncomplex numbers ↳ quotient
and remainder tuple
float(x) ↳ a floating point number
from an integer or string; if x="1.1"
print(float(x)*2) ↳ 2.2
hex(x) ↳   int to hex string
hex(65536) ↳ 0x10000 or
hex(65536)[2:] ↳ '10000'
oct(x) ↳   int to octal
int(x) ↳ int from float, string, hex
pow(x,y [,z]) ↳ x to y, if z is
present, returns x to y, modulo z
pow(5,2)=25, pow(5,2,7)=4
round(number [,digits]) floating
point number rounded to digits or
nearest integer if digits not used
round(3.14159, 4) ↳ **3.1416**
max, **min**, **sort** - see data containers
None -> **constant** for null; x=None

String Tools

Built-In Functions
ascii(str) ↳ like repr, esc non-ascii
chr(i) ↳ character of Unicode 97= 'a'
input(prompt) ↳ user input as str
len() ↳ length of str; count of iter-
able items (list/dictionary/tuple/set)
ord(str)↳ value of Unicode char.
repr(object) ↳   printable string
str(object) ↳   string val of object

---

slice selection: **str[:**stop**]; str[**start**:**stop**
[:**step**]]** ↳ a string created by the selection
String Formatting
.format() - *see Format Toolbox!*
method: (1) substitution (2) pure format
(1) '***string {sub0}{sub1}'**.format(0, 1)
print("Give {0} a {1}".format('me','kiss'))
(2) '**{:**format_spec**}'**.format(*value*)
function: format (*value, spec*)
format_spec: (format mini-language string)

[[**fill**] **align**] [**sign**] [# - alt form] [0-**forced
pad**] [**width**] [**,**] [**.precision**] [**type**]

x= **format**(12345.678, **" =+12,.2f"**)
↳ + 12,345.68
NEW in 3.6   **f-strings:**
print(**f"**{'Pay $'}{9876.543: ,.2f}**"**)
↳ Pay $ 9,876.54 |format strings|
.center(width[, fillchar]) string centered in
width area using fill character 'fillchar'
.capitalize() ↳   **F**irst character capitalized
.ljust(width [, fillchar]) or **.rjust(**same args**)
.lower()/.upper()** ↳ change case
.strip; *or* **.lstrip;** *or* **.rstrip;** + (**[chars]**) ↳
a string with all *or* leading, *or* trailing,
[chars] removed. If [chars] included, all are
removed. If [chars] omitted or None, the
argument removes whitespace
.swapcase() ↳ cases exchanged
.title() ↳ **F**irst **W**ords **C**apitalized
.zfill(width) - left fill with '0' to len width
String Methods
Str "**.is**" tests—(**Note**: tested here for char-
acters 0 to 255) ↳ *True* if all chars in the
string meet attribute condition and string
=>1 character in length. ↳ False if Null
.isalnum()—True if all chars in a string are
either .isalpha(), .isnumeric(), .isdigit() or
.isdecimal() *Note False if your number
contains a decimal point: to vet a variable
v1 as a float: if (type (v1) == float): or
convert in a **try/except** structure
.isalpha()—upper and lower case normal
letters plus 64 printable characters between
chr(170) and chr (255)
.isdecimal()—digits 0,1,2,3,4,5,6,7,8,9
.isdigit()—0 to 9 plus superscripts ^{2} (178),
^{3} (179), and ^{1}(185)
.isidentifier()—tests a string to see if it is a
valid Python identifier or keyword
.islower()—lower case ltrs plus 36 printable
characters between chr(170) and chr(255)
.isnumeric()—.isdigit plus ¼ (188),
½ (189), and ¾ (190)
.isprintable()—189 of the 256 characters
between 0 and 255 starting with the space
chr(32) sequentially to ~ chr(126), then chr
(161) to (255) except for chr(173)
.isspace()—true for chrs (9-13), (28-32),
(133) and (160). Note space: " " is chr(32)
.istitle()—for all practical purposes, every
word in a string begins with a capital letter
.isupper()—normal upper case plus 30
printable characters between chr(192-222)
.casefold() ↳ casefold - caseless matching
.count(sub[,start[,end]]) # of substrings
.encode(encoding="utf-8", errors="strict"**)
.endswith (suffix[, start[, end]])** ↳ **T/F**
.expandtabs() replace tabs with spaces
.find(sub[, start[, end]]**)** ↳ the index of
substring start, or -1 if it is not found;
print('Python'.find("th")) ↳ 2
.index(sub[,start[,end]]) = .find but failure

---

to find sub causes *ValueError*
seperator.**join([string list])**
joins strings in iterable with **sep**
char; can be null
.partition(sep) ↳ 3 tuple: **before,
sep, after**
[new 3.9] .removeprefix(prefix,/)
and **.removesuffix**(suffix,/)
.replace(old, new[, count]) ↳
substring old replaced by new in object;
if count is given, only the count
number of values are replaced
.rfind(sub[, start[, end]]) ↳
lowest index of substring in slice
[start:end]. -1 on fail
.rindex()rfind but fail ↳ *ValueError*
.rsplit— like **split,** except splits
from right
.split([sep] [maxsplit=]) ↳ word
list, default sep is space(s)
.splitlines(keepends=False) ↳
list of lines broken at line
boundaries
.startswith(prefix[,start[,end]]**)**
↳ True/False prefix can be a tuple
.translate(table) map to table
made with **.maketrans**(x,[,y[,z]])

Looping

while (*expression evaluates as True*)**:**
    process data statements; **else:**
break ends <u>while</u> loop, skips else:

for *expression to be satisfied*: ex:
**alist=['A','B','C']; x=iter(alist)
for i in range (len(alist)):**
    print(i+1, next(x)) *can use **else:**
else: while and **for** support else:
**range (start, stop [,step])
continue** skips to next loop cycle

Decision Making

**if   elif   else:
if** somenum == 1**:** # do this code
elif somenum == 2**:** # do this code
else:
   # otherwise do this code
The ternary if: an inline **if** that
can be use in formulas
print(x **if** x **in** myword **else** "", end="")

Error Management

use in error handling blocks
try: code with error potential
except *error type*: code if this error
else: otherwise do this code
finally: do this either way
assert: condition = **False** will raise
an *AssertionError*
raise forces a specified exception

List Comprehensions

Make a new list with exclusions and
modifications from an existing list or
tuple: brackets around the expression,
followed by 0 to *many* **for** or **if** clauses;
clauses can be nested:
new_list = [(modified**)item for item in
old_list if some-item-attribute of (item)]**
atuple=(1,-2,3,-4,5)
mylist=**[**item*2 for item in atuple if item>0**]**
print(atuple, mylist)
↳ (1, -2, 3, -4, 5) [2, 6, 10]
if modifying items only:
up1list =**[**x+1 for x in L**]**

Data Containers
Methods & Operations

↓ Usually: i,j,k: indexes x: value or object
L / T / D / S / F / SF ↳ **instances** of:
list, tuple, dictionary, set, frozen set, both
Unique Data Type Statements/Methods

LISTS: [ ] - Ordered, Mutable
 create **L**=[]; **L**=**list**(**L/T/S/F**); **L**=[[**x** [,**x**]…]]; **L**=**L**[i:j:k] *list from slice*; **list**(**D**) ↳ list of all dictionary keys
 add/remove members .**append**(x) where x is string or data object; **L1** + **L2** *concatenate (lists only)*; **insert**(i[th] member, as new element); .**copy()** *duplicate list*; .**pop(i)** *return & remove i[th] item, last item if no i*; .**clear()** *remove all mem-bers*; .**extend** (iterable) *adds iterable members; strings add letters as members*;
 query **L**[x] ↳ *value at position x, can be multiple values: a,b=L[2:4]*; **L.index** (**x**[,*at/after index* **i**][,*before index* **j**]) ↳ *slice position of string or value x in list, ValueError if not in found*; .**count(x)** *find number of instances of x in list*; **min**(**L**); **max**(**L**); **len**(**L**); x **in L**; x **not in L**;
 manipulate .**sort(**key=none/function, reverse=False); **sorted(L**[,reverse]); **L.reverse()** *reverse item order*;

TUPLES: ( ) - Ordered, Immutable
 create **T**=**()**; **T**=(x,[[**x**],(x)…**]**); **T**=**tuple**(**T/L/S/F**);
 add members +=(**x**,[**x**]) *add 1 or more items, note comma for 1 item*; **T1** + **T2** *concatenate (tuples only)*;
 query =**T**[**i:j**] *get slice values, end is last item + 1*; .**count(x)** *find number of instangces of x in tuple*; **T.index(x**[,*at/after index* **i**][,*before index* **j**]) ↳ *slice position of possible member x,*; **min**(**T**); **max**(**T**); **len**(**T**); x **in T**; x **not in T**;
 manipulate **sorted** (**T**, *reverse=T/F*); **T**[::-1] *reverse order* ;

DICTIONARIES: { } Mutable, Mapped, Unordered, Unique keys in Pairs
  k ↳ 'key', v ↳ 'value':
 create **D**={k:v, [,k:v]}; =**dict**(i=j [,k=l]); =**dict**(zip(L1, L2**)**); **D2**=**D1.copy()**; =**dict.fromkeys** (**L/T/F** , *pair members with v/None/ iterable*);
 add/remove members **D**[k]=*new_value*; **D.update**(**D2**) *add D2 items to D replacing dup values*; **D**=(****D| **D2**); **D.setdefault**(k[,default]) *return value if k in dict, if not, insert and return default*; **D.clear()**; del **D**[k] *remove member*; **D.pop**(k) ↳ v and removes k; new **[3.9]**: **D**=**D2|D3**; **D|**=k/v pairs;
 query see setdefault also; x=**D**[k] ↳ v or keyerror if no k; x=**D.get**(k[,x]) *like D [k] but* ↳ x if no k; **len**(**D**); **D**ictionary views: **D.keys()**; **D.values()**; **D.items()**; *for item view, x* ↳ *a (key, value)* **tuple**; *keys, values, items can all be* **iterated x in** D.*view*; **x not in** D.*view*;
 manipulate **D**[existing k]=**value** *change value*; **[new in 3.8]** *where ri is a reversed iterator* **ri**=**reversed**(**D**.*view*) *iterate with next(ri); output sorted using* **sorted(D.items())**

SETS: *Unique, Mutable*, Unordered
FROZENSETS: *immutable after creation;*
 create S=**{**x,x,x**}**; S=**set**(**L/T/F**); S='string' ↳ unique letters
 create F=**frozenset**([iterable]) ☞ *only*
 *add/remove members*
Set only S.**add**(i); S.**remove**(element) *Key Error if missing*; S.**discard**(element) *no error if missing*; S.**pop()** *remove/return random element*; S.**clear()**; S.**update**(iterable); *or* S1 |= S2; *These add members from iterable(s) or set(s).* S.**intersection_update(**other iterables**)**; *or* S1 &= S2; *Keep universal elements.* S.**difference_update**(iterable) *or* S1 -= S2 *Remove members found in others.* S.**symmetric_difference_update**(iterable) S1 ^= S2; *keep unique elements only*

DIFFERENCE   **Visual Set Concepts**
INTERSECTION   DISJOINT
SUPERSET
SUBSET

Sets & Frozensets
SF.**copy()** *Return a shallow copy.*
SF.**union**(**SF**2) *or* **SF**3=**SF**1|**SF**2[|…] merge the sets
SF.**intersection**(**SF**2) *or* **SF1** & **SF2** intersection of S1 & S2
SF.**difference**(**SF**2) *or* **SF**-**SF**2 *unique in* **SF**
SF.**symmetric_difference**(**SF**2) *or* **SF^SF**2 *elements in either but not both*
 query (**Sets & Frozensets**) len(**SF**); Boolean Tests: **x in SF**; **x not in SF**; **SF**.**isdisjoint**(**SF**2) T if no common items **SF**.**issubset**(**SF**2) & **SF1**<=**SF2** One set is contained by the other
SF1<**SF2** set is a proper subset
SF1.**issuperset**(**SF2**) *or* **SF1**=>**SF**2 Every element of SF1 in SF2
SF1>**SF2** set is a proper superset

*/** for iterable (argument) unpack
* for list/tuples, ** for dictionaries; Ex:
a,*b,c = [1,2,3,4,5]; ↳ a=1, c=5, **b**=[2,3,4]
d1={1:'a', 2:'b'}; **d2**={2:'c', 3:'d'} ;
d1={****d1**, ****d2**} *or new in* [**3.9**] **d1|**=**d2** ↳ **d1**={1:'a',2:'c',3:'d'}

More Data/Iterable Tools
all(iterable)↳ True if all elements are True
any(iterable) ↳ True if any element is True *all and any are both FALSE if empty*
del(iterable instance) - delete
enumerate(iterable, start = 0**)** ↳ tuples list alist = ['x','y','z']; l1 = list(enumerate(alist)); print(l1) ↳ **[(0,'x'), (1,'y'), (2,'z')]**

Use enumerate to make a dictionary. ex: mydict = dict(enumerate(mylist))

filter(function, iterable) selector for elements for which function is True
iter and **next(iterator ,default])** create iterator with **iter**; fetch items with **next** ; default returned if iterator exhausted, or StopIteration ⚑
team = ['Amy', 'Bo', 'Cy']; it1 = iter (team); myguy = ""
while myguy is not "Cy":   ↳ Amy
   myguy = next(it1, "end")   Bo
   print(myguy)   Cy

map(function, iterable) can take multiple iterables - function must take just as many
alist=[5,9,13,24]; x = **lambda** z: (z+2)
list2 = list(map(x, alist)); print(list2)
↳ [7, 11, 15, 26]

range ([start,] stop [,step])
alist=["**Amy**","Bo","Cy"]   0 Amy
for i in **range** (0, len(alist)):   1 Bo
   print(str(i), alist[**i**]) # note slice   2 Cy

reversed**()** reverse **iterator**: list or **tuple**
alist=["A","B","C"]; print(alist)   ['A', 'B', 'C']
alist.**reverse**(); print(alist);   ['C', 'B', 'A']
rev_iter = **reversed**(alist)   A, B, C,
for letter in range(0, len(alist)):
   print(next(rev_iter), end=", ")

sum(iterable [, start]) all numeric
ex: if a=[8,7,9] then sum(a) ↳ 24
type([iterable]) ↳ object datatype
zip() creates aggregating iterator from multiple **iterables**, ↳ iterator of tuples of ith iterable elements from each sequence or iterable

Other Object Commands
Working with object attributes (most useful for created class objects)
getattr(object, 'name' [, default])
listatr = getattr(list, '__dict__')
for item in listatr:
   print(item, listatr[item], sep=" | ")
setattr(object, 'name', value)
hasattr(object, 'name')
delattr(object, 'name')
exec(string or code obj[, globals [, locals]) dynamic code execution
compile(source, filename, mode, flags=0, don't_inherit=False, optimize=-1) create a code object that **exec**() or **eval**() can execute
hash(object) ↳ integer hash value if available
dir() ↳ names in current local scope
dir(object) ↳valid object attributes

*args and *kwargs:
used to pass an unknown number of arguments to a function.
*args is a **list**   arg#1: B
def testargs (a1, ***argv**):   arg#2 is C
   print('arg#1: ', a1)   arg#3 T
   for ax in range(0, len(**argv**)):   arg#4 is A
      print ("arg#"+str(ax+2)+" is "+**argv[ax]**)
testargs('B', 'C', 'T', 'A')

*kwargs is a **keyword -> value pair** keyword is **not** an expression
def testkwargs(arg1, ****kwargs**):   formal arg: 1
   print ("formal arg:", arg1)   ('dog', 'cat')
   for key in **kwargs**:   ('arg2', 'two')
      print ((key, **kwargs**[key]))
testkwargs(arg1=1, arg2="two", dog='cat')

Example of: function, *, *args
def myfunc(*args): # function unknown # args
   print(*args)
my_list = ['a1','b2','x','c3'] # create list
myfunc(*my_list) # new list expanding old
del my_list[2]   # remove 2nd item
myfunc(*my_list)   # reprint to prove

User Functions

def create function: def functName(args):
return(variable object) - return the value a function derived **- or -**
yield/next; in a generator function, returns a **generator** with sequential results called by **next**
global x creates global variable - defined <u>inside</u> a function
nonlocal a variable in a nested function is valid in an outer function

Creating a Function
(required in red, optional in green)
(examples: return & generator functions)
   ☞ ***command key word*** ☞ **arguments**
*1 def *name* (input or defined params):
   ☞ new *function name*   *colon*☞
*2 """a docstring""" (can be multiline)
*2-x or 3-x code block
*last return(expression to pass back)
or a ***generator*** passed using **yield:**
vowels, myword = 'aeiouy','idea'
def gen1(wordin):
  for letter **in** wordin:
    yield(letter)
for x **in** gen1(vowels):

   ┌─────────┐
   │ ↳ **aei** │
   └─────────┘

  print(x **if** x **in** myword **else** "", end="")
  next

Lambda: unnamed inline function

lambda [parameters]**:** expression
z = lambda x: format(x**3,",.2f");
print(**z**(52.1))   ↳ **141,420.76**

CLASS - an object **blueprint** or **template**
(required in red, optional in green)
Common components of a class include:
*1 *inheritance creates a* ┐ *"derived class"*
   ☞*command key word* ↓ *colon* ☞
class class-name (inheritance) :
   your class name ☜ *class* **definition header**
Class creates a namespace and provides
<u>instantiation</u> and <u>attribute reference</u>
*2 a **docstring**, '"Docstring example"'
*3 instantiation with **special method:**
   def __init__(self, arguments):
autoinvoked when class is created; Arguments are passed when a class instantiation is called. Includes variable name assignments, etc.
*4 function definitions and local variable assignments   example:
❶ class mammalia(object):
❷   "A class for mammal classification"
❸   def __init__(self, order, example):
       self.ord = order
       self.ex = example
       self.cls="mammal"
❹   def printInfo(self):
       info="class/order: " + self.cls + "/"+\
          self.ord +", Example: " + self.ex
       print(info)
mam_instance = mammalia("cetacea","whales")
mam_instance.printInfo()

❺ **class/order: mammal/cetacea, Example: whales**

File Access

wholefilepath="C:\\file\\mytest.txt"
open(file[,mode],buffering])
   helpful methods: **.readline(),**
read(size), .readlines(), .write (string), .close(), list(openfile), .splitlines([keepends]),
with open(wholefilepath) [as textfile]:
   textfile=mytest.read().splitlines()

WITH structure closes a file automatically
*Many other functions **not** shown here*

Functions * boldface not in this basic toolbox

abs()	callable()	enumerate()

Other Built-in Functions

definition: ITERABLE: an object that can return members 1 at a time
pass (placeholder – no action)
del deletes variables, data containers, items in iterables: del mylist[x]
breakpoint enters debugger - **with** wrapper ensures **_exit_** method
eval(Python expression) ↳ value
bool(expression) ↳**T/F**(F default)
callable(object) ↳**T**rue if it is
help(object) invokes built-in help system, (for interactive use)
id(object) ↳ unique identifier
:= (**New [3.8]**) - assignment expression operator assigns values to variables inside a larger expression
bytearray([source[, encoding [, errors]]]) ↳ a new bytearray; source can be an iterable of integers 0 to 255, an integer defining array size, or a string witn encoding which will be converted to bytes using **str.encode()**
globals() ↳ a dictionary of current global symbols of the current module
isinstance(object, classinfo**)** ↳ True if object is an instance of classinfo
issubclass(object, classinfo**)** ↳ True if object is a subclass of classinfo
locals() ↳ a dictionary of the current local symbol table
vars([object]) ↳ the **__dict__** attribute for a module, class, instance or object

Operators and Precedence

lambda
if – else
or · and · not x Boolean OR, AND, NOT
in · not in · is · is not
< · <= · > · >= · != · ==
| · ^ · & bitwise OR, XOR, AND
<< · >>
+ · -
* · @ · / · // · % (Multiplication, matrix multiply, division, floor div, remainder)
+x · -x · ~x (pos, neg, bitwise NOT)
**   (exponentiation)
await x   (Await expression)
x[index] · x[index:index] · x(argu-ments...)
x.attribute (subscription, slicing, call, attr ref)

Basic Open File Modes: *open for*
'r' reading (default)
'w' writing, truncating the file first
'x' exclusive creation, fails if it already exists
'a' writing, appending to the end of the file **if** it exists
'b' binary mode
't' text mode (default)
'+' for updating (reading and writing), ie. "r+" or "w+"

Built-in Types
numerics, sequences, mappings, classes, instances, exceptions

Numeric Types
int   float   complex constructors:
complex(real, imaginary) *imaginary defaults to 0*

Numeric Operations
x + y	sum of x and y	**x - y**	difference of x and y
x * y	product of x and y	**x / y**	quotient of x and y

x // y   floored quotient of x and y
x % y   remainder of x / y   **-x** x negated
+x x unchanged   **abs(x)** absolute value x
int(x) x converted to integer
float(x) x converted to floating point
complex (real, imaginary) imaginary defaults to 0
c.conjugate() conjugate of complex number c
divmod(x, y)   the pair (x // y, x % y)
pow(x, y) x to the power y
x ** y x to the power y
round(x[,n]) round to n digits, half to even
math module (import math) adds these operations:
math.trunc(x); math.floor(x); math.ceil(x)

Sequence Operations (4.6.1)
x in s True if an item of s is equal to x
x not in s False if an item of s is equal to x
s + t   the concatenation of s and t
s * n or n * s concatenate s n times
s[i]   ith item of s, origin 0
s[i:j]   slice of s from i to j
s[i:j:k]   slice of s from i to j with step k
len(s)   length of s
min(s)   smallest item of s
max(s)   largest item of s
s.index(x[, i[, j]]) index of the first occurrence of x in s (at or after index i and before index j)
s.count(x) number of occurrences of x in s

Mutable Sequence Operations
s[i] = x   item of s is replaced by x
s[i:j] = t   slice of s from i to j is replaced by the contents of the iterable t
del s[i:j]   removes i to j; same as *s[i:j] = []*
s[i:j:k] = t   the elements of s[i:j:k] are replaced by those of t; start, stop, step
del s[i:j:k] removes the elements of s[i:j:k] from the list
s.append(x) appends x to the end of the sequence
s.clear()   removes all items from s (same as *del[:]*)
s.copy()   creates a shallow copy of s (same as *s[:]*)
s.extend(t) or *s +=* extends s with the contents of t (for the most part the same as *[len(s):len(s)] = t)*
s *= n   updates s with its contents repeated n times
s.insert(i, x) inserts x into s at the index given by i(same as *s[i:i] = [x]*)
s.pop([i])   retrieves the item at i and removes it from s
s.remove(x) remove the first item from s where s[i]== x
s.reverse() reverses the items of s in place
** see: https://docs.python.org/3.6/library/stdtypes.html

Keywords (reserved) and, as, assert, async, await, break, class, continue, def, del, elif, else, except, False, finally, for, from, global, if, import, in, is, lambda, nonlocal, None, not, or, pass, raise, return, True, try, while, with, yield
Built-in Constants   False, True, None, NotImplemented, Ellipsis (same as literal '...'), __debug__, quit(), exit(), copyright, credits, license

f-string Formatting : [new 3.6]

conversion types

'd'	Signed integer decimal.
'i'	Signed integer decimal.
'o'	Signed octal value.
'u'	Obsolete type – it is identical to 'd'.
'x'	Signed hexadecimal (lowercase).
'X'	Signed hexadecimal (uppercase),
'e'	Floating point exponential format (lowercase).
'E'	Floating point exponential format (uppercase).
'f'	Floating point decimal format.
'F'	Floating point decimal format.
'g'	Floating point format. Uses lowercase exponential format if exponent is less than -4 or not less than precision, decimal otherwise
'G'	Floating point format. Uses uppercase exponential format if exponent is less than -4 or not less than precision, decimal format otherwise.
'c'	Single character - accepts integer or single character str
'r'	String - uses repr() to convert object
's'	String - uses str() to convert object
'a'	String - uses ascii() to convert object
'%'	Puts '%' character before result

conversion flags

'#'	conversion will use "alternate form"
'0'	conversion zero padded for numerics
'-'	value is left adjusted (overrides '0')
' '	(space) Leave a space before a + or #
'+'	A sign character ('+' or '-') will precede conversion (overrides "space" flag).

Boolean Operations

Operation / Result (ascending priority**)**

x **or** y	if *x* is false, then *y*, else *x*
x **and** y	if *x* is false, then *x*, else *y*
not x	if *x* is false, True, else False

Integer Bitwise Operations

Operation / Result

x | y	bitwise *or* of *x* and *y*
x ^ y	bitwise *exclusive or* *x* and *y*
x & y	bitwise *and* of *x* and *y*
x << n	*x* shifted left by *n* bits
x >> n	*x* shifted right by *n* bits
~x	the bits of *x* inverted

Bytes and Bytearray Operations

x. = means this method can be used with "bytes." or "bytearray." i.e., x.count(*sub*[, *start*[, *end*]]) is same as *bytes.count(sub[, start[, end]]) or bytearray.count(sub[, start[, end]])*
- x.decode(encoding="utf-8", errors="strict")
- x.endswith(suffix[, start[, end]])
- x.find(sub[, start[, end]])
- x.index(sub[, start[, end]])
- x.join(iterable)
- static bytes.maketrans(from, to)
- static bytearray.maketrans(from, to)
- x.partition(sep)
- x.replace(old, new[, count])
- x.rfind(sub[, start[, end]])
- x.rindex(sub[, start[, end]])
- x.rpartition(sep)
- x.startswith(prefix[, start[, end]])
- x.translate(table, /, delete=b")
- x.center(width[, fillbyte])
- x.ljust(width[, fillbyte])
- x.lstrip([chars])
- x.rjust(width[, fillbyte])
- x.rsplit(sep=None, maxsplit=-1)
- x.rstrip([chars])
- x.split(sep=None, maxsplit=-1)
- x.strip([chars])

- x.capitalize()
- x.expandtabs() (tabsize=8)
- x.isalnum()
- x.isascii()
- x.isalpha()
- x.isdigit()
- x.islower()
- x.isspace()
- x.istitle()
- x.isupper()
- x.lower()
- x.splitlines (keepends=False)
- x.swapcase()
- x.title()
- x.upper()
- x.zfill(width)

Errors

ArithmeticError	DeprecationWarning	LookupError	SystemError

The Python Standard Library

Content: docs.python.org/3/py-modindex.html

Text Processing Services - 7 modules including:
- **string** — Common string operations
- **re** — Regular expression operations
- **textwrap** — Text wrapping and filling

Binary Data Services - 2 modules

Data Types – 13 modules including:
- **datetime** — Basic date and time types
- **calendar** — Calendar-related functions
- **copy** — Shallow and deep copies
- **enum** — Support for enumerations
- **pprint** — Data pretty printer

Numeric and Mathematical Modules – 7 modules including:
- **numbers** — Abstract base classes
- **math** — Mathematical functions
- **cmath** - complex #; decimal - accurate
- **random** — Generate pseudo-random #s
- **statistics** — Statistical functions
- **fractions** — Rational numbers

Functional Programming – 3 modules

File and Directory Access – 11 modules including:
- **pathlib** — Object-oriented file paths
- **os.path** — Common path functions
- **fileinput** — iterate lines—multiple inputs
- **filecmp** — File and directory compare
- **shutil** — High-level file operations

Data Persistence – 6 modules including:
- **pickle** — Python object serialization
- **marshal** — Internal Python object serialization
- **sqlite3** — DB-API 2.0 interface for SQLite databases

Data Compression and Archiving – 6

modules including:
- **zipfile** — Work with ZIP archives
- **tarfile** — Read and write tar archive files

File Formats – 5 modules including:
- **csv** — CSV File Reading and Writing

Cryptographic Services – 3 modules:

Generic Operating System Services – 16 modules inc:
- **os** — Miscellaneous operating system interfaces
- **time** — Time access and conversions
- **io** — Core tools working with streams
- **platform** — Accesss to platform identifying data

Concurrent Execution – 10 modules including:
- **threading** — Thread-based parallelism
- **multiprocessing** — Process-based parallelism

Interprocess Communication and Networking - 9 mods **Internet Data Handling –** 10 modules:

Structured Markup Processing Tools – 13 modules:

Internet Protocols and Support - 21 modules

Multimedia Services – 9 modules including:
- **wave** — Read and write WAV files

Internationalization – 2 modules:

Program Frameworks – 3 modules including:
- **turtle** — Turtle graphics

Graphical User Interfaces with Tk – 6 modules including:
- **tkinter** — Python interface to Tcl/Tk
- **IDLE**

Development Tools – 9 modules:

Debugging and Profiling – 7 modules:

Software Packaging and Distribution – 4 modules including: distutils — Building and installing modules
- **ensurepip** — bootstrapping pip installer

Python Runtime Services – 14 modules including:
- **sys** — System-specific parameters and functions
- **sysconfig** — Access to Python's config information
- **__main__** Top-level script environ.
- **inspect** — Inspect live objects

Custom Python Interpreters – 2 mods

Importing Modules – 5 modules including
- zipimport — Import modules from Zip archives
- **runpy** — Locating and executing Python modules

Python Language Services – 13 mods :
- **keyword** — Testing for Py keywords
- **py_compile** — Compile Python source files

Miscellaneous Services – 1 module:

MS Windows Specific Services – 4 modules

Unix Specific Services - 13 modules:

Superseded Modules – 2;

Undocumented Modules – 1

pypi.org another 257M+ modules including: RPI.GPIO, Pillow, pandas, fuzzywuzzy, Anaconda, miniconda, conda, playsound, Poetry, Numpy, etc.

To find installed modules from Python: **>>> help('modules')**

Selected Standard Library Module Constants and Methods for New Users

calendar import calendar

a couple of fun examples:
```
c=calendar.TextCalendar(calendar.SUNDAY)
c.pryear(2021,w=2,l=1,c=6,m=3)          or try
c=calendar.TextCalendar(calendar.MONDAY)
c.setfirstweekday(calendar.SUNDAY)
print(c.formatmonth(2021,1,w=0,l=0))
```
many functions - **see: www.wikipython.com** -> OTHER MODULES -> calendar

cmath - A suite of functions for complex #

copy - import copy relevant for compound objects, (objects containing other objects)
- .**copy**(x) <-relies on references to objects
- .**deepcopy**(x[, memo]) <-copies objects (so you can change the copy and not the original)

csv import csv comma separated values
- .**reader**(csvfile, dialect='excel',**fmtparams) *file and list objects ; file obj opens with newline=""*

.reader objects: **csv.reader(file path). +**
__next__() , dialect , line_num , or fieldnames
.**writer**(csvfile, dialect='excel',**fmtparams)
writer objects: csv.writer(file path). +
writerow(row) , writerows(rows) , dialect , or writeheader()
.**list_dialects**() - *return registered dialect names* includes classes to read/write dictionary objects

Constants: .QUOTE_ALL, .QUOTE_MINIMAL, .QUOTE_NONNUMERIC, .QUOTE_NONE

datetime import datetime

Constants: MINYEAR, MAXYEAR

From datetime import timedelta: tools for duration and difference between dates and times.

Supports functions for the following **types: .date, .time, .datetime, .timedelta., .tzinfo, .timezone**

Minimum constructor:datetime.datetime(year,month,day);
To create today's date object: datetime.date.**today**();

Escapes

\	newline
\\	backslash
\' \"	quote sgl/db
\a	ascii bell
\000	octal val 000
\xhh	hex value hh

Module Management

import get module, ex: import math
from get a single module function:
from math import cos; print (cos(9))
as creates an alias for a function

object attributes: .year, .month, .day (iyr=idte.year)
Get a time tuple: **datetime.datetime.timetuple**(arg)
ex: ↳ time.struct_time(tm_year=2020, tm_mon=7, tm_mday=26, tm_hour=11, tm_min=10, tm_sec=0, tm_wday=6, tm_yday=208, tm_isdst=-1)
ex: Using timedelta to find a future date:
start = **datetime.date(2019, 1, 1)**
duration = **datetime.timedelta**(days=180)
enddate = start + duration
print(enddate)   ↳ **2019-06-30**
with idte=datetime.datetime.**today**(), instance attributes are: .year, .month, .day, .hour, .minute, .second, .microsecond, .tzinfo, .fold ex: idte.minute
much more - *also in **PyPi** see new **python-dateutil** module

decimal   fast, correctly rounded fp math with a gazillion functions and pages of instruction

ensurepip - boostrap pip into an existing Python environment - pip is the installer for modules **not in the Standard Library**
Windows **command line invocation**:
python –m ensurepip -- upgrade

enum - from enum import enum
mimicks enum in C, fast integer access and iter.

filecmp   import filecmp
.cmp(f1, f2, shallow=True) Compare f1 and f2, returning True if they seem equal

fileinput   import fileinput
  for line in fileinput.input():
   process(line)
.input (files=None, inplace= False, backup="", *, mode='r', openhook=None)
.filename() ↳ file being read
.fileno() ↳ file descriptor (-1 is none open)
.lineno() ↳ cumlatiave # of last line read
.filelineno() ↳ line # in current
.isfirstline() ↳ True if first line of its file
.isstdin() ↳ True if last line was read
from sys.stdin
.**nextfile**() close file, read next line from next file
.**close**() close

fractions.py   import fractions
.Fraction (numerator=0, denominator=1)
.Fraction(other_fraction)
.Fraction(float)
.Fraction(decimal)
.Fraction(string)
a= '22' ; print(fractions.Fraction(a))   ↳ 11/50
print(fractions.Fraction(math.pi))
   ↳ 884279719003555/281474976710656

idlelib   IDLE is Python's native IDE   see:
https://docs.python.org/3.6/library/idle.html

io   import io *three types: text, binary, raw*
for example: *continued next page*
f = open("myfile.txt", "r", encoding="utf-8")
f = open("myfile.jpg", "rb")
f = open("myfile.jpg", "rb", buffering=0)

json - import json   **methods include:**
.loads(str,...) - json str to Python dict and objects
.dumps(obj,…) - Py dictionary and nested objects converted to json string for storage
.load(fp,...) - json obj from file converted to Python dict and other obj(s)
.dump(obj, fp,...) - encode Py obj(s), save to file

keyword   import keyword
.**iskeyword**(str)   **.kwlist**   *(note no prens)*

math - import math   functions include:
.ceil(x) *smallest int >= x*
.comb(n,k) *ways to choose k items from n*
.copysign(x,y) *absolute value of x, sign of y*
.fabs(x) ↳ *absolute value of x*
.factorial(x) ↳ *x factorial as integer*
.floor(x) ↳ *largest int <= x*
.fmod(x,y) *mathematically precise ver of x%y*
.frexp(x) ↳ *mantissa and exponent of x (m,e)*

.fsum(iterable) *returns fp sum of values*
.gcd(a,b) ↳ *greatest common divisor of a & b*
.isclose(a, b, *, rel_tol=1e-09, abs_tol=0.0) *True if a & b are close, otherwise False, relative or abs tolerance*
.isfinite(x) ↳True if x not infinity or a NaN
.isinf(x) *True if x is a positive or negative infinity*
math.isnan(x) ↳ True if x is a NaN (not a number), False otherwise.
[new 3.8] .isqrt(n) ↳*the integer square root of the nonnegative integer n. This is the floor of the exact square root of n, or equivalently the greatest integer such that a² ≤ n. To compute the ceiling of the exact square root of n, a positive number, use a = 1+ isqrt(n - 1).*
.ldexp(x, i) ↳ *x * (2**i); inverse of **frexp**()*
.modf(x) ↳ fractional and integer parts of x
.trunc(x) ↳Real value of x truncated to integral
.exp(x) ↳ e**x.
.expm1(x) ↳ e**x - 1
.log(x[, base]) 1 argument, ↳ natural logarithm of x (to base e). 2 arguments, ↳ the logarithm of x to the given base, calculated as log(x)/log(base).
.log1p(x) ↳ the natural logarithm of 1+x (base e). *accurate for x near zero*
.log2(x) ↳ the base-2 logarithm of x
.log10(x) ↳ base 10 log of x
.pow(x,y) ↳ x raised to y
.sqrt(x) ↳ square root of x
Trigonometric Functions: ↳**radians .atan2**(y,x)
.hypot(x,y) ↳ sqrt(x*x + y*y) **.acos**(x) **.asin**(x)
.atan(x) **.cos**(x) **.sin**(x) **.tan**(x)
.degrees(x) anglex from radians to degrees
.radians(x) anglex from degrees to radians
Hyperbolic Functions: ↳**radians**
.acosh(x) ↳ the inverse hyperbolic cosine of x
.asinh(x) ↳ the inverse hyperbolic sine of x
.atanh(x) ↳ the inverse hyperbolic tangent of x
.cosh(x) ↳ the hyperbolic cosine of x
.sinh(x) ↳ the hyperbolic sine of x
.tanh(x) ↳ the hyperbolic tangent of x
Constants:
math.pi π = 3.141592…   **math.e** e = 2.718281…
math.nan A floating-point "not a number" (NaN)
[New 3.6] math.tau τ = 6.283185…
[New 3.5]math.inf A floating-point positive infinity. (For negative infinity, use -math.inf.)

numbers - operations from abstract base classes - four classes defined: Complex(compon-ents: real, imaginary), Real, Rational (adds numerator and denominator properties), Integral

os   import os ****hundreds of functions, many os specific; a few universal**
.environ['HOME'] *home directory*,
.chdir(path) change working dir
.getcwd() current working dir
.listdir(path)   **.mkdir**(path)   **.mkdirs**(path)
make all intermediate directories   **.remove**(path)
.strerror()   translate error code to message
.curdir()   **.rename**(src, dst)   **.rmdir**(path)
.walk(start directory, topdown=True) produces a generator of filenames in a directory tree
.system(command) Unix and Windows, execute the command in a subshell

os.path *Lib/posisxpath or Lib/ntpath (windows)*
import os.path [as osp]
.abspath(*path*) normalized absolutized version of the pathname *path*.
.basename(*path*) base name of pathname *path*.
.commonpath(*paths*) longest common sub-path.**commonprefix**(*list*) ↳ the longest prefix
.dirname(*path*) ↳ directory name of *path*
.expandvars(*path*) ↳ *environment variables expanded*
.exists(*path*) ↳ True if *path* exists
.getsize(*path*) ↳ n the size, in bytes, of *path*.
.isabs(*path*) ↳True if *path* is absolute pathname
.isfile(*path*) ↳ True if *path* is existing file

.isdir(*path*) ↳ True if *path* is existing directory
.islink(*path*) ↳True if ref is an existing directory
.join(*path*, **paths*) Join one or more path components intelligently.
.normcase(*path*) Normalize case of a pathname
.normpath(*path*) On Windows, converts forward slashes / to backward slashes \.
.relpath(*path*, *start=os.curdir*) ↳ relative filepath from the current directory or an optional start
.samefile(*path1*, *path2*) ↳ True if both pathname arguments refer to the same file or directory.
.sameopenfile(*fp1\fp2*) ↳   True if the same
.samestat(*stat1*, *stat2*) Return True if the stat tuples *stat1* and *stat2* refer to the same file.
.split(*path*) Split *path* into a pair, (head, tail)
pathlib (3.5) from pathlib import Path [as pt]
(For PurePath objects see online documentation.)
For MOST of the following concrete **methods** use:
.cwd() ex: my_current_dir = pt.cwd();   **.home**()
For a user defined file the following functions require that the file variable first be instantiated with the Path class; i.e., for "myfile" holding "C:\temp.txt": test_file = **pt**(myfile), then, **pt.exists** (test_file) is noted just as: **.exists (test_file)**
is_dir(test_dir)   **.is_file**(test_file)
*** *.glob—in our testing .glob does NOT work outside the **sorted()** wrapper:*
    print(sorted(p.**glob**(test_file, "*.py")))
.iterdir() - creates an iterator; for directory x:
for dir in x.iterdir(): print(dir)
.mkdir (mode=0o777, parents=False, exist_ok=False) create new directory F
.open(mode='r', buffering=-1, encoding= None, errors=None, newline=None)
.read_text();   **.rename(target)**;   **.rmdir()** - remove empty directory   **(file_path).resolve (strict=False)** - make absolute path
.write_text(data, encoding=None, errors=None) - *open, write, close - all in one fell swoop*

pickle import pickle - non-human-readable object serialization (**json** is text strings only)
.dump(obj.file, protocol=None, *,fix_imports=True, buffer_callback=None)
.dumps(obj, protocol=None, *, fix_imports=True, buffer_callback=None)
.load(file, *, fix_imports=True, encoding="ASCII", errors="strict", buffers=None)
.loads(data, *, fix_imports=True, encoding="ASCII", errors="strict", buffers=None)

platform   import platform
.machine() ↳ *machine type*
.node() ↳ *network name*
.processor() ↳ *real processor name*
.python_version ↳ *version as string*
.system() ↳ *'Linux', 'Darwin', 'Java', 'Windows'*

pprint import pprint
allows output of objects, including objects holding other objects in a reasonably readable format. Begin by creating an instance: (assume "mylist")
pp = **pprint.PrettyPrinter**(indent=3) *set indent*
then use your instance ("pp" above) to output:
pp.**pprint**(mylist)
some PrettyPrinter objects new/changed in **[3.8]**
.pformat(obj), .pprint(obj), pp.isreadable(obj), more
ex: print(pp.**isreadable**(mylist))

py_compile.py import py_compile
.compile(file) - the compiled file is placed on file path in added directory "/__pycache__/ "

random   import random
only for non-cryptographic applications
.seed initialize the random number generator
.getstate() ret object with internal generator state
.setstate() restores internal state to getstate value
.getrandbits(k) ret integer with k random bits
For integers:
.randrange(stop)   **.randrange**(start, stop[, step])
.randint(a, b) fileinput.filename() a random integer N such that a <= N <= b. Alias

Column 1

for randrange(a, b+1).
For sequences:
.choice(sequence) ✎ random element
.shuffle(x [,random]) shuffle sequence in place
.random() ✎ the next random floating point number in the range (0.0, 1.0).
.uniform(a, b) ✎ fp between a and b

re import re complex search and match
re.**search**(pattern, string, flags=0)
re.**match**(pattern, string, flags=0)
re.**ignorecase**

shutil import shutil
.copyfileobj(fsrc, fdst[, length])
.copyfile(src, dst, *, follow_symlinks=True)
.copymode(src, dst, *, follow_symlinks=True)
Copy the permission bits from src to dst.
.copystat(src, dst, *, follow_symlinks=True)
Copy the permission bits, last access time, last modification time, and flags from src to dst
.copy(src, dst, *, follow_symlinks=True)
Copies the file src to the file or directory dst. src and dst should be strings.
.copy2(src, dst, *, follow_symlinks=True)
copy2() also attempts to preserve file metadata
.copytree(src, dst, symlinks=False, ignore=None, copy_function=copy2, ignore_dangling_symlinks= False, dirs_exist_ok=True)
.disk_usage(path) ✎ disk usage stats as tuple (total, used and free) in bytes—a file or a directory

Sound if your objective is to play a sound using a Python Standard Library module save your time - **none** of the modules listed under Multimedia Services do that. SEE: PyPi — playsound

sqlite3 import sqlite3
initialize using the Connection cursor() object:
conn = sqlite3.**connect**("'database_name'.db")
use special name **:memory** *to create in RAM*
cur = **conn.cursor** #create cursor object,
connection objects: cursor(), **commit**()., **rollback**(), **close**(), **execute**(), **executemany**(), **backup**()**executescript**(), **create_function**(), **iterdump**(), **create_aggregate**()
cursor objects: execute(), executemany(), executescript(), fetchone(), fetchmany(), fetchall() or close()
row objects: keys()

statistics import statistics
.mean(data) average
.harmonic_mean(data) harmonic mean
.median(data) middle value
.median_low(data) low middle value
.median_high(data) high middle value
.median_grouped(data) 50th percentile
.mode(data) most common
.pstdev(data,mu=None) population std dev
.pvariance(data,mu=None) pop variance
.stdev(data, xbar=None) sample std dev
.variance(data, xbar=None) sample variance
more...extensive normal distribution functions

string

Constants
string.ascii_letters,
string.ascii_lowercase string.ascii_uppercase
string. digits string.hexdigits
string.octdigits string.punctuation
string.printable string.whitespace

string.**capwords**(str, sep=None)

sys import sys mostly advanced functions
.exit([arg]) - exit python
.getwindowsversion()
.path - search paths list
.version - Python version #

tarfile import tarfile extensive archive including gzip, bz2 and lzma compression
ex: (assumes import tarfile – to extract to cwd)
tar = tarfile.**open**("sample.tar.gz")
tar.**extractall**()
tar.**close**()

Column 2

textwrap import textwrap
textwrap.**wrap**(text,width=x,**kwargs)**Lib/Lib/**
time import time or from time import
a new user must understand terminology found at:
https://docs.python.org/3.8/library/time.html
print(time.**time**()) #seconds since the epoch
 ✎ 1596486146.111275
mytime = time.**time**() #capture it
print(time.**localtime**(mytime)) #demo the tuple
 ✎ time.struct_time(tm_year=2020, tm_mon=8, tm_mday=3, tm_hour=16, tm_min=22, tm_sec=26, tm_wday=0, tm_yday=216, tm_isdst=1)
time_tuple=time.**localtime**(mytime) #capture it
print("The hour is: " **+** str(time_tuple[3])) #demo
 ✎ The hour is: 16
print(time.**strftime**("%a, %d %b %Y %H:%M:%S +0000", time.**gmtime**()))
 ✎ Mon, 03 Aug 2020 20:22:26 +0000
seconds=5 ; print("Wait 5 seconds!")
time.**sleep**(seconds) # delay of five seconds
print(time.**asctime**(time.localtime()))
 ✎ Mon Aug 3 16:22:31 2020
print(time.**ctime**(mytime))
 ✎ Mon Aug 3 16:22:26 2020

tkinter from tkinter import *
**there is a 10 page tkinter toolbox available to review at www.wikipython.com with a link to a free download on GitHub

wave import wave
.open(file, mode=None) If file is a string, open the file by that name, otherwise treat it as a file-like object. mode can be: 'rb' (read), 'wb' (write) ex:
with wave.**open**("D:\\aloop.wav", "rb") as tstfile:
 print(tstfile.**getnframes**()) # length in frames
once an object is returned by open(),
wave_read objects have these methods:
.close() i.e., object.close **.getnchannels**()
.getsampwidth() **.getframerate**() **.getnframes**(n)
.readframes(n) **.rewind**()
wave_write objects have these methods:
.close() Make sure nframes is correct
.setnchannels(n) **.setsampwidth**(n) -
.setframerate(n) **.setnframes**(n) Set frames to n.
.setparams(tuple) tuple should be (nchannels, sampwidth, framerate, nframes, comptype, compname), with values valid for the set*() methods. Sets all parameters.
.tell() Return current position in the file
.writeframesraw(data) Write audio frames, without correcting nframes.¶

A Few PyPi Modules https://pypi.org

Anaconda, Conda, MiniConda - 3 related programs offering environment management at different levels. **Anaconda** manages all variations and compatibility issues unavoidable with many modules. Over 300 applications come "installed" in the base (root) environment, with thousands available. **Installation(s) can be huge.** It qualifies as a language within itself. Numerous IDEs are available in any Anaconda environment including Spyder, Visual Studio Code, IDLE, Jupyter Notebooks ... more. **Miniconda** is a lightweight version. **Conda** is similar to pip but is also an environment manager.

NumPy - powerful **N-dimension array** objects NumPy says installation works best with a prebuilt package, see: https://scipy.org/install.html where they suggest a "scientific distribution" but do give **pip** directions: python -m pip install --user numpy scipy matplotlib ipython jupyter pandas sympy nose obviously adding a whole bunch of other modules but violating the best advice of Jonathan Helmus at Anaconda, *"avoid all 'users' installs."* so... with conda: *from the Anaconda prompt type: conda install numpy* (did not test this)

Column 3

with pip: *python –m pip install numpy* (worked ok)
import numpy as np
.array([elements list][element list][...])
.zeros(# of 0 elements)
.ones(# of 1 elements)
.empty(# of elements, values are random)
.arange(# of elements) np.arange(5)✎([0,1,2,3,4])
.linspace(start, stop, # of elements) <-linearly spaced: .linspace(2,10,5) ✎([2,4,6,8,10])
dtype - default datatype is fp, but can specify with dtype: xarray = np.ones(3, **dtype**=np.int)
np.**sort**(array variable)
.ndim the # of axes/dimensions, of the array
.size the total number of elements of the array
.shape a tuple of integers indicating # of elements in each dimension
one zillion more functions

***For Raspberry Pi Aficionados**

Rpi.GPIO – module to control Raspberry Pi GPIO channels; see GPIO toolbox and download link at: **www.wikipython.com**

Pillow - by Alex Clark, updated Aug 2020, a friendly version of Fredrik Lundh's **Python Imaging Library** Pillow version 7.2 works in Python 3.5 to 3.8
install: **python3 -m pip install --upgrade Pillow**
from PIL import Image
im = Image.**open**(testfilepath)
print(im.**format**, im.**size**, im.**mode**)
im.**show**()

playsound is a cross platform program pulled from **Pypi** that is very easy to use. From windows:
python -m pip install playsound for example:
 from playsound import playsound
 testwave = "C:\\Windows\\Media\\Alarm09.wav"
 playsound(testwave)

Poetry is a smaller more efficient way to manage dependencies for 3.4+ but it's a little complicated. Start with: https://pypi.org/project/poetry/

pandas for tabular data — "aims to be the fundamental" module for "real world data analysis" - it is part of the Anaconda distribution (also installs with Miniconda) but can be installed with pip:
pip install pandas then **import pandas as pd**
tables are **DataFrame**(s) and columns are **Series**
see the docs @: https://pandas.pydata.org/
finance) import yfinance as yf
*NOTE—a few functions no longer work
create stock instance with **.Ticker**(stock symbol)
ex: jnj = yf.Ticker("JNJ") *i.e.[Johnson & Johnson]*
.history(period ="short cut symbol") valid periods
1d,5d,1mo,3mo,6mo,1y,2y,5y,10y,ytd,max **or**
.history(start="yyyy-mm-dd", end="yyyy-mm-dd")
.actions - dividends, splits
.dividends or **.splits** - show dividends or splits
.financials or **.quarterly_financials**
.major_holders **.institutional_holders**
.calendar **.recommendations**

plotly.express and **Kaleido** - **plotly.express** is built-in to the **plotly** library and is considered a "starting point" but may be all you ever need. *Plotly is an MIT Licensed module.* plotly.express requires a determined effort to learn because it creates more than 35 types of graph images. It does **not** export your graph as a static image—which is why you need **Kaleido**. plotly has many dependencies, kaleido has none. pip install kaleido.

What is not mentioned in this General Toolbox?
About 99.83% of Python capability now available has no mention in this toolbox. Happy Coding!

Can methods of your favorite module be briefly summarized?
Please send your suggestion(s)!
